Abstract 
Seventy two (72) sexed crossbred rabbits aged 6 months were used to determine the effect of ginger rhizome powder (GRP) supplementation on reproductive organ and serum sex hormonal characteristics of pubertal rabbits. The experimental rabbits were divided into 2 treatment groups comprising 36 males and 36 females. Each group was divided into 4 dietary treatments (BT, BT, BT, and BT) of 9 animals and replicated thrice with 3 animals per replicate in a completely randomized design (CRD). The animals were fed formulated diet containing 2900 Kcal ME kg⁻¹ and 18% crude protein supplemented with GRP at the rate of 0, 5, 10 and 15 g kg⁻¹ feed respectively. Rabbits in each dietary group were fed 50gms of Guinea grass leaf meal containing 27.6% CF (dry matter basis) occasionally as additional fibre sources. Feed and water were offered ad libitum and the study lasted for 10 weeks. Testosterone values of BT (5.83 ng mL⁻¹) and BT (6.28 ng mL⁻¹) and follicle stimulating hormone (FSH) levels of BT (1.15 mIU mL⁻¹) were significantly influenced (p<0.05) by ginger rhizome powder. Bucks on BT, and BT had lower luteinizing hormone (LH) level than the BT, bucks. For the females, FSH and LH values ranged significantly (p<0.05) from 0.90 to 2.05 mIU mL⁻¹ and 0.90 to 3.15 mIU mL⁻¹ respectively. The 17β - estradiol and progesterone levels also ranged significantly (p<0.05) from 166.35 to 175.05 pg mL⁻¹ and 15.45 to 16.80 ng mL⁻¹ respectively. Ovarian weight of rabbit on BT was significantly (p<0.05) higher than those on BT but similar to those on BT, and BT, treatments. It was therefore concluded that the use of ginger rhizome powder in rabbit diets improved the weight of the ovary as well as enhances serum progesterone, estrogen and testosterone levels.

Keywords: Ginger, rabbits, ovary, testosterone, estrogen, progesterone

Introduction
High levels of production and efficient feed conversion are the needs of the modern animal industry which, to a certain extent, could be achieved by the use of specific nutritive and non nutritive feed additives. Antibiotic growth promoters have been included in livestock diets to promote growth, health and to maximize the genetic potentials of farm animals (Bozkurt et al., 2008). However, the development of drug resistant micro organisms in humans has compelled animal nutritionists and feed millers to search for alternative plant extracts as growth promoters in monogastric animals (Denli et al., 2003). Researchers (Denli et al., 2003) have identified several beneficial active ingredients in medicinal plants and herbs which play important roles in improving production and immune system of animals against diseases, and could be effectively utilized as natural growth promoters to replace antibiotics. These plants, spices and fruits include garlic, ginger, pepper and bitter kola, among others. Specifically, ginger has been extensively investigated...
and their properties documented (Zhang et al., 2009; Zhao et al., 2011). Ginger belongs to the family Zingiberaceae and also is a major crop grown primarily in China, India and Nigeria, and exported worldwide. Ginger leaves are linear, and the flowers are lemon green in colour. It is a well known herb widely used as a spice all over the world (Bartley and Jacobs, 2000) and in medical treatment for certain ailments in traditional medicine (Zhang et al., 2009). Ginger contains several phytochemical compounds which have biological activities such as antioxidation, antimicrobial and other pharmacological effects (Zhao et al., 2011).

This study was therefore; designed to examine the effect of dietary ginger rhizome powder supplementation on reproductive organ and sex hormone characteristics of pubertal rabbits.

Materials and Methods

This experiment was conducted at the Rabbit Unit of the Teaching and Research Farm, Department of Animal Science and Technology, Federal University of Technology, Owerri, Nigeria. Geographically, Imo State is located on latitude 4° 4’ and 6° 3’ N and longitude 6° 15’ and 8° 15’E. Fresh ginger rhizomes of the Indian cultivar Himachel pradesh were procured from National Root Crops Research Institute (NRCRI), Umudike, Abia State. The processing method used is according that described by Ogbuewu et al. (2013). Milled ginger rhizome powder was collected and stored in a polyethylene bag for use in feed supplementation.

Experimental animals used in this study were 72 crossbred pubertal rabbits (36 males and 36 females), aged 6 months. The animals were housed 3 rabbits per cage in a two tier hutch with wooden / wire mesh floor. A 14 –day pre –treatment period was used to acclimatize the animals to the experimental procedure. The 72 sexed rabbits were divided into two major groups comprising 36 males and 36 females. Each group was further divided into 4 groups (BT, BT, BT, and BT) of 9 rabbits each, replicated 3 times with 3 rabbits per replicate in a completely randomized design (CRD). The nutrient composition of the experimental diet is as presented in table 1. The other 3 dietary groups were given the same diet as fed to the control groups, but supplemented with GRP at 5 g (BT), 10 g (BT), and 15 g (BT) per kilogram feed. Rabbits in each dietary group were fed 50gms of Guinea grass leaf meal containing 27.6% CF and 6.05% ash on dry matter basis occasionally as additional fibre sources. Feed and water were offered ad libitum and the study lasted for 10 weeks.

The blood samples used for this study were taken from marginal ear vein of the experimental rabbits at the end of the trial, between the hours of 8 am and 9 am before feeding. The blood samples were collected into a set of sterile plastic bottles and allowed to coagulate to produce sera for

hormonal analyses. The test for hormonal parameters in the blood serum (Testosterone, luteinizing hormone (LH), follicle stimulating hormone (FSH), progesterone, and estrogen) were carried out with the aid of the tube based enzyme immunoassay (EIA) method. The protocol used for the hormone assay was according to the method of Micaleft et al. (1995) as described for the kit (BioCheck ELISA Assay, USA).

At the end of the 10 weeks feeding trial, one female rabbit from each of the replicates, making three per treatment, was fasted for 12 hours, weighed, slaughtered and dissected following standard procedure (Karbe and Skottke, 1985). The ovaries were collected, trimmed free of fats and adhering connective tissues. The ovary organ was weighed with an electronic precision balance (Model L2200P) and the weights expressed as percentages of live body weight. The histopathological examination of the ovarian tissue was carried out at the Histopathology Laboratory, Federal Medical Centre, Owerri, as described by Drury and Wallington (1976).

The data obtained were subjected to Analysis of Variance (ANOVA) in a completely randomized design (CRD) using a computer software (SAS, 1999). Differences between means were separated using Duncan's New Multiple Range Tests (DNMRT (Steel and Torrie, 1980).

Results and Discussion
Data on male sex hormones profile of pubertal rabbits fed GRP supplemented diets are presented in Table 2. There were significant (p<0.05) difference in FSH levels measured, these values however did not follow pattern. Bucks in BT₁ recorded significantly (p<0.05) higher LH value (0.65 mIU mL⁻¹) than bucks in BT₂ (0.30 mIU mL⁻¹) and BT₃ (0.10 mIU mL⁻¹). The serum testosterone values ranged significantly (p<0.05) from 3.93 to 6.28 ng mL⁻¹. The serum testosterone values recorded in this study compared favourable with the range of 2.51 to 2.88 ng mL⁻¹ reported for male rabbits fed coconut ash supplemented diets (Iwu et al., 2013). According to Osinowo (2006) and Ogbuewu et al. (2011), circulating testosterone in the male are produced primarily in the gonads under the influence of FSH and LH. The observed increase in testosterone levels of BT₂, BT₃ and BT₄ bucks is an indication that ginger rhizome powder probably contains some androgenic analogue which acts on hypothalamus to stimulate testosterone release from the testes through the action of gonadotropin releasing hormone (GnRH) and luteinizing hormone.

The effect of ginger rhizome powder supplemented diets on serum hormones profile of female rabbits are presented in Table 3. The LH values were found within the range of 0.90 – 3.15 mIU mL⁻¹. The LH levels were negatively influenced (p<0.05) by the treatments. The FSH values ranged significantly (p<0.05) from 0.90 to 2.05 mIU mL⁻¹. The progressive decline in FSH and LH values suggest that ginger rhizome powder supplementation reduces the serum circulating FSH and LH levels. Interestingly, the dose related decrease in LH level in the current study agrees with earlier reports of Kiuchi et al. (1982) in rats administered ginger powder. The dose related decrease in LH and FSH value of female rabbits observed in this study could also be an indication that some of the bioactive ingredient (s) contained in ginger may have negatively influenced the synthesis and release of these hormones.
into the blood. According to Osinowo (2006), the circulating LH in the female is responsible for maintaining normal plasma estradiol and progesterone concentration.

The concentrations of progesterone in the current work were within the range 15.45 to 16.80 ng mL\(^{-1}\). Rabbits fed diet supplemented with ginger rhizome powder at 5 g kg\(^{-1}\) feed showed a significant (p<0.05) increase in the progesterone level as against the rabbits fed control and BT\(_2\) diets. The values increased with ginger rhizome powder supplementation at 5 g kg\(^{-1}\) feed (16.80 ng mL\(^{-1}\)) but declined slightly at 10 g kg\(^{-1}\) feed (16.55 ng mL\(^{-1}\)) and 15 g kg\(^{-1}\) feed (15.57 ng mL\(^{-1}\)). Also, BT, and BT\(_2\) had higher (p<0.05) serum 17ß-estradiol levels compared to the groups fed 0 g kg\(^{-1}\) and 15 g kg\(^{-1}\) feed. Highest serum 17ß-estradiol value was achieved in the group fed ginger rhizome powder diet at 10 g kg\(^{-1}\) supplementation rate. These results are in harmony with Hsia et al. (2007) who reported that administration of some medicinal plant extract in rabbit increased circulating 17ß-estradiol and progesterone level. Progesterone helps to regulate the oestrus cycle, prepare the female for conception and pregnancy (Osinowo, 2006). The increase in the concentration of blood 17ß-estradiol with supplementation of ginger rhizome powder in this study could therefore be attributed in part to increased metabolic activity in the supplemented animals, probably induced by increased uptake and assimilation earlier recorded in these animals (Ogbuewu et al., 2010; Ogbuewu, 2012).

The results of the ovarian weight of female rabbits fed GRP supplemented diets are presented in figure 1. The ovarian weight of BT\(_3\) females was significantly higher (p<0.05) than those of BT\(_1\) but similar to those on BT\(_2\) and BT\(_4\) treatments. From these results, supplementation of GRP at 5 g kg\(^{-1}\) feed, 10 g kg\(^{-1}\) feed and 15 g kg\(^{-1}\) feed increased the ovarian weight by 50%, 100% and 50%, respectively relative to the control group. These findings were in agreement with the earlier reports of Bitto and Gemade (2001), and Ogbuewu (2008) that nutrition influences ovarian functions in rabbits. The significant increase in the ovarian weight of BT\(_3\) (10 g kg\(^{-1}\) feed) group over those in BT\(_1\) (0 g kg\(^{-1}\) feed) group was an indication that 10 g kg\(^{-1}\) feed could be the optimal inclusion level of GRP needed to enhance ovarian functions.

the ovary recorded in this study compared favourably with the value (0.05 – 0.12 g) reported by Osuagwu (2004) and Ogbuewu (2008) in growing rabbits. The significantly higher ovarian weight recorded in BT, corresponds with the highest estradiol value. This confirms earlier report Iwu et al. (2013) of increased metabolic activity of the ovary with increased nutrient uptake and assimilation in growing rabbits.

Results of ovarian histopathological photomicrograph of rabbits fed GRP supplemented diets are presented in Plate 1, 2, 3 and 4. Histopathological assessment of the ovaries revealed pictures of normal structural materials associated with complete oogenesis. The histological integrity of the ovary is fundamental to the

production of fertile ova. Any factor(s), which damages the ovaries such as infections, toxic agents or malnutrition will result in the production of sub-fertile ova. Histological sections of the ovary in all the groups revealed normal ovary with numerous primordial follicles in the cortical areas. In this study, the pre-antral follicles were fully formed. The stroma was lutenized. All the ovarian tissues were suggestive of normal ovary with follicle development and ovulation. No lesions were observed, atretic follicles were less visible and normal olive green colour of ovaries was maintained. The present study revealed that groups fed ginger rhizome powder at 5, 10 and 15 g kg\(^{-1}\) feed had no evidence of histopathological alterations in the cytoarchiteture of the ovaries.

**Conclusion**

The result of ovarian morphometry revealed that ginger rhizome powder supplementation at 5, 10 and 15 g kg\(^{-1}\) feed could improve the weight of the ovary indicating that up to 15 g kg\(^{-1}\) feed ginger rhizome powder supplementation would support better ovarian development in rabbits. This was associated with increased serum testosterone, progesterone and estrogen concentration indicating, probably a ginger rhizome powder inducement of improved metabolic activity. The current study also revealed that 10 g kg\(^{-1}\) feed was the optimal ginger rhizome powder supplementation rate in female rabbits, since this led to improved weight of ovary. This was equally associated with increased estrogen concentration, which decreased with increasing ginger rhizome powder supplementation.
